Abstract

Background: Anemia is a common complication among patients with chronic kidney disease (CKD), especially those who are on hemodialysis. It also has a marked effect on their Quality of Life and with it, the morbidity-morbidity. This research aimed to evaluate the frequency and incidence of anemia in hemodialysis patients at IKD

Objectives: to find out the incidence and etiological factors responsible for anemia in hemodialysis patients at IKD

Study design: a cross-sectional study

Duration and place of study. From 05- June 2023 to 05-Aug 2023 department of urology institute of kidney diseases Peshawar

Methods

This study was designed as a cross-sectional analysis on 200 hemodialysis patients of IKD Demographics, clinical parameters and laboratory values were collected. Anemia was characterized by an hemoglobin <13 g/dL in men and <12 g/dL for women. Statistical Analysis: Descriptive statistics, including mean and standard deviation assisted by the p-value for determining significance.

Results

Out of 200 Patients had a mean age of 58.4 years (SD =12.6). 85% of patients had anemia, with a mean hemoglobin 10.2 g/dL (SD 1.4) in anaemic patient's. The main causes of anemia were iron deficiency (60%), inflammatory states (40%) and erythropoietin resistance(alone or in combinations) for 25%, respectively. Anemia prevalence was significantly associated with all the comorbidities and with increased duration of hemodialysis.

Conclusion

Anemia is highly prevalent among hemodialysis patients at IKD, most often attributed to iron deficiency and inflammation. Treatments are effective as long the condition can be caught early and so, regular monitoring is vital for a more positive prognosis. Additional investigation is necessary to improve anemia care in this population.

Introduction

Anemia is a common and serious complication in patients with chronic kidney disease (CKD), especially hemodialysis. It has a profound impact on the quality of life of patients, and carries high morbidity and mortality rates as well as considerable healthcare costs. Anemia prevalence estimates among CKD patients range from 30% to 90%, depending on the stage of kidney disease and criteria used for defining anemia [1]. The potential causative factors of anemia in patients undergoing hemodialysis are multifactorial and include decreased erythropoietin, iron deficiency, chronic inflammation while anticoagulation during dialysis leads to blood loss. [2] Erythropoietin, a hormone created by the kidneys that increases red blood cell formation in bone marrow. The injured kidneys in CKD cannot produce enough erythropoietin, which reduces red blood cell production and induces anemia [3]. Furthermore, patients undergoing hemodialysis (HD) frequently suffer from iron deficiency caused by inadequate dietary intake, poor absorption and chronic blood loss during the dialytic procedure [4-5]. Anemia can also be promoted by inflammatory cytokines that are known to be increased in patients with CKD, which often affect erythropoiesis [6]. Chronic kidney disease (CKD)-associated anemia is associated with a variety of adverse outcomes such as increased cardiovascular morbidity and mortality, cognitive decline, decreased physical capacity to exercise [7]. Management of anemia in hemodialysis patients commonly includes erythropoiesis-stimulating agents (ESAs) and iron treatment [8]. But the response to these therapies is variable, and many patients remain anemic despite therapy [9]. Sources of Iron Deficiency and Prevalence among Hemodialysis Patients The commonness reasons for iron lack in hemodialysis patients have been comprehensively shown to incorporate the accompanying [10] Metropolitan Medical Center a tertiary care hospital IKD Peshawar that offers full

Kidney disease treatment including hemodialysis services. Thus, the objective of this study was to evaluate the prevalence and identifying reasons for anemia in hemodialysis patients at IKD. Through the identification of these primary contributors to anemia in this population, we aim to optimize anemia management and increase burden among patients [11].

Methods:

This was a cross-sectional study conducted at IKD that included 100 hemodialysis patients. The study period was six months. Inclusion criteria were patients 18 years old or above and who had been receiving hemodialysis treatment for at least three months. Exclusion criteria included acute kidney injury or other acute illnesses that affected hemoglobin levels.

Collected data

Collected data was comprised of demographics, clinical parameters, and laboratory values. Anemia was defined as hemoglobin levels of less than 13 in males and 12 in females. The levels of serum ferritin, transferrin saturation, erythropoietin dosage, and inflammatory markers were also recorded.

Statistical analysis

Statistical analysis was conducted using SPSS 24.0 software, and data was summarized using Descriptive statistics. The Student's t-test was used to study the difference between groups in terms of continuous variables, while the chi-square test was used for categorical variables, and the considered significance value p was less than 0.05.

Results:

The mean age of the study population was 58.4 years SD 12.6, and 60% were male, while 40% were female; as presented in Table 1. The duration of exposure to hemodialysis was 4.3 years (2.7), and 85% of patients had anemia, while the average hemoglobin levels were 10.2

g/dL 13.5 g/dL 1.4 in anemic patients compared to non-anemic patients. The leading cause of anemia includes iron deficiency at 60%, Inflammatory state at 40%, and epoetin resistance at 25%. Patients who have been on hemodialysis for more than five years had a higher prevalence of anemia at 90% as opposed to patients on hemodialysis for a period of fewer than five years at a level of 75% and $p=0.026$, while those with diabetes had a prevalence of 88% as opposed those without it at an 80% with a non-significance level of $p=0.09$.

Table 1: Demographic Characteristics of Study Population

Characteristic	Total (n=200)
Age (years), mean (SD)	58.4 (12.6)
Gender, n (%)	
Male	120 (60%)
Female	80 (40%)
Duration of Hemodialysis (years), mean (SD)	4.3 (2.7)

Table 2: Prevalence of Anemia

Anemia Status	Total (n=200)
Anemic, n (%)	85 (85%)
Non-Anemic, n (%)	15 (15%)
Hemoglobin (g/dL), mean (SD)	
Anemic	10.2 (1.4)
Non-Anemic	13.5 (1.2)
p-value	<0.001

Table 3: Causes of Anemia

Cause of Anemia	Total (n=170)
Iron Deficiency, n (%)	120 (60%)
Inflammatory States, n (%)	64 (40%)
Erythropoietin Resistance, n (%)	16 (25%)

Table 4: Association with Clinical Parameters

Parameter	Anemic (n=170)	Non-Anemic (n=30)	p-value
Duration of Hemodialysis > 5 years, n (%)	76 (90%)	4 (75%)	0.02
Duration of Hemodialysis < 5 years, n (%)	9 (10%)	11 (25%)	
Presence of Diabetes, n (%)	75 (88%)	12 (80%)	0.09
No Diabetes, n (%)	10 (12%)	3 (20%)	

Discussion

In this study, we show that the percentage of anemia among all hemodialysis patients who are receiving care at IKD is equal to 85%(n-170) for

scale(parameters =metric) and blood(parameters =biologic_pt). This is broadly consistent with previous studies showing 70-90% prevalence of anemia in hemodialysis populations, underlining the substantial burden that this condition poses for CKD patients. Mean hemoglobin levels in anemic patients were significantly lower than non-anemic patients (10.2 g/dL vs 13.5 g/d), which reflects the severity of anemia in this cohort Iron deficiency explained more than half of anemia among all patients(variable 1) both in the unit and back to home(Tabklet2), in accordance with similar findings showing iron as a main problem for hemodialysis, secondary causes may be inadequate dietary intake. impaired absorption or frequent blood losses during sessions(hemodiafiltration). [15]. This study further underlines the importance of frequent iron status monitoring and adequate supplementation with iron in this patient group.About 40% of patients with anemia had inflammation as the second most common cause. Pro-inflammatory cytokines, such as interleukin-6 (IL-6) and tumor necrosis factor-alpha (TNF- α), which are stimulated during inflammatory states in patients with CKD can blunt erythropoiesis [16]. These cytokines cause the production of hepcidin, a hormone that inhibits iron absorption and release from stores with consequent anemia. This effect was not unexpected as inflammation in anemia of CKD has been well described [17] and fits with our results. Twenty-five percent of anemic patients were erythropoietin resistant. When anemia does not respond to treatment with erythropoiesis-stimulating agents (ESAs) the condition is referred to as functional or absolute iron deficiency which accounts for a large proportion of all ESA-resistant cases, and it may be related in half of these patients resistant by inflammation but also other comorbidities such diabetes mellitus and/or cardiovascular disease [18]. Consistent with prior studies demonstrating that patients on long-term dialysis and those with diabetes are at increased

risk for resistance to erythropoietin [19], our study identified the independent significance of longer duration of hemodialysis or presence of diabetes as predictive determinants associated with anemia. Anemia is driven more by iron deficiency than erythropoietin hyporesponsiveness among lower dialysis dose chronic kidney disease patients on extended hemodialysis. Hematopoiesis in Longer Dialysis Patients - Am J Physiol Renal the American Society of Nephrology. Already have an account with NSI.org? This long-term study finding highlights the need for regular anemia screening and appropriate therapeutic intervention in patients undergoing extended hemodialysis sessions. Similar trends have been noted in previous studies, suggesting that the cumulative effects of factors such as blood loss and inflammation lead to anemia progressing over time due to iron deficiency [20]. Notably, though anemia was more prevalent in diabetics (88%), this association did not reach statistical significance; $p=0.09$. This might be complicated - perhaps due to the small sample size, or other confounders. However, we found a positive association between diabetes and anemia in CKD which is well known that diabetes predisposes to the development of anemia largely through autonomic neuropathy affecting erythropoietin production from kidneys [21].

Conclusion:

this study reveals the complex pathophysiology of anemia in patients on maintenance hemodialysis: iron deficiency; inflammation with immune response and increased hepcidin levels; as well resistance to metabolically active EPO. Monitoring and managing these factors aggressively is vital to optimize anemia outcomes in this population. More prospective studies are needed to investigate on new therapeutic strategies and interventions aimed at treating anemia in these patients under hemodialysis.
